| Abstract | This article investigates the impact of wage dispersion on firm productivity in different working        |
|          | environments. More precisely, it examines the interaction with: (i) the skills of the workforce, using   |
|          | a more appropriate indicator than the standard distinction between white- and blue-collar workers,       |
|          | and (ii) the uncertainty of the firm economic environment, which has, to our knowledge, never been       |
|          | explored on an empirical basis. Using detailed cross-sectional linked employer-employee data for         |
|          | Belgium, we find a hump-shaped relationship between (conditional) wage dispersion and firm               |
|          | productivity. This result suggests that up to (beyond) a certain level of wage dispersion, the incentive |
|          | effects of 'tournaments' dominate (are dominated by) 'fairness' and/or 'sabotage' considerations.        |
|          | Findings also show that the intensity of the relationship is stronger for highly skilled workers and     |
|          | in more stable environments. This might be explained by the fact that monitoring costs and               |
|          | production-effort elasticity are greater for highly skilled workers, and that in the presence of high    |
|          | uncertainty, workers have less control over their effort-output relation, and associate higher           |
|          | uncertainty with more unfair environments.   |
